3 BACKGROUND

In this section, we introduce our problem and our exposition language, Agda.

module POPL19 where

open import Helpers.DataProperties

open import Function using (_o_)

open import Data.Nat

open import Data.Fin as Fin hiding (_+_)

open import Data.Vec as Vec hiding (map)

open import Relation.Binary.PropositionalEquality

A (*non-dependently-typed*) *signature* is what programmers refer to as an ‘interface’: It is a collection of ‘sort’, or type, symbols; along with a collection of ‘function’ symbols, and a collection of ‘relation’ symbols. For our discussion, we are only interested in single-sorted non-relational signatures, which means there is only one anonymous sort symbol and a collection of function symbols. In Agda:

record Signature₀ : Set₁ where

field

FuncSyms : Set

arity : FuncSyms → ℕ

In a dependently-typed language, we may simplify this further since a pair $A \times (A \rightarrow B)$ corresponds to a *single* dependent type $A' : B \rightarrow \text{Set}$.

record Signature₁ : Set₁ where

field

{- “FuncSyms n” denotes the function symbols of arity “n”. -}

FuncSyms : (n : ℕ) → Set

Of-course a one-field record is silly, so we simplify further:

Signature : Set₁

Signature = ℕ → Set

Here is a few examples of signatures: ||

2020. 2475-1421/2020/1-ART1 \$15.00

<https://doi.org/>

```

50 data TypeS : Signature where
51
52 data UnaryS : Signature where
53   next : UnaryS 1
54
55 data MagmaS : Signature where
56   _◦_ : MagmaS 2
57
58 data PointedS : Signature where
59   point : PointedS 0
60
61 {- Pointed Magma -}
62 data SemigroupS : Signature where
63   Id : SemigroupS 0
64   _◦_ : SemigroupS 2
65
66 {- Alias -}
67 MonoidS : Signature
68 MonoidS = SemigroupS
69
70 {- Pointed Unary Magma -}
71 data GroupS : Signature where
72   Id : GroupS 0
73   _ : GroupS 1
74   _◦_ : GroupS 2
75
76 Just as a signature can be construed as an interface, an algebra can be thought of as an imple-
77 mentation:
78
79 record _Algebra (FuncSyms : Signature) : Set1 where
80   field
81     Carrier : Set
82     reify    : ∀ {n : ℕ} (f : FuncSyms n) → Vec Carrier n → Carrier
83
84 open _Algebra
85
86 {- syntactic sugar -}
87 infixl 5 [[_]]_$ _
88 [[_]]_$ _ : {FuncSyms : Signature} {n : ℕ} → FuncSyms n → (A : FuncSyms Algebra)
89           → Vec (Carrier A) n → Carrier A
90 [[ f ]] A $ xs = reify A f xs
91
92 Here are two examples algebra:
93
94 numbers : TypeS Algebra
95 numbers = record { Carrier = ℕ ; reify = λ { () _ } }
96
97 additive-ℕ : SemigroupS Algebra
98 additive-ℕ = record { Carrier = ℕ
99   ; reify = λ { Id [] → 0; _◦_ (x :: y :: []) → x + y }
100 }
```

To define the notion of *free algebra*, we only need the concept of *homomorphism*: Functions that preserve the interpretations of the function symbols.

```
record _Homomorphism (FuncSyms : Signature) (Src Tgt : FuncSyms Algebra) : Set where
  field
    map          : Carrier Src → Carrier Tgt
    preservation : ∀ {n : ℕ} {f : FuncSyms n} {xs : Vec (Carrier Src) n}
      → map (⟦ f ⟧ Src $ xs) ≡ ⟦ f ⟧ Tgt $ Vec.map map xs
```

```
open _Homomorphism
```

```
{- Syntactic Sugar -}
```

```
_ $\langle$ $⟩_ : {S : Signature} {Src Tgt : S Algebra}
  → (S Homomorphism) Src Tgt → Carrier Src → Carrier Tgt
h  $\langle$ $⟩ xs = map h xs
```

We are now in a position for our prime definition: One says \mathcal{A} is a *free S -algebra* for a type G of ‘generators’ provided \mathcal{A} is an S -algebra that ‘contains’ G and every S -homomorphisms $\mathcal{A} \rightarrow \mathcal{B}$ correspond to functions $G \rightarrow \text{Carrier } \mathcal{B}$.

```
record _free-for_ {S : Signature} (A : S Algebra) (G : Set) : Set1 where
  field
    embed      : G → Carrier A
    extend     : {B : S Algebra} → (G → Carrier B) → (S Homomorphism) A B
    {- “Homomorphisms are determined by their behaviour on embedded elements.” -}
    uniqueness : {B : S Algebra} (H : (S Homomorphism) A B) → H ≡ extend (map H ∘ embed)

    restrict : {B : S Algebra} (H : (S Homomorphism) A B) → G → Carrier B
    restrict H g = H  $\langle$ $⟩ embed g
```

This paper aims to solve \mathcal{A} free-for G where \mathcal{A} is the unknown.

An interface generally comes with a collection of coherence laws enforcing desirable behaviour. Likewise, we want to speak of “equational algebras”. This requires we speak of “equations”, which are pairs of “terms”:

```
data _Term-over_ (S : Signature) (X : Set) : Set where
  var : X → S Term-over X
  _$ _ : {n : ℕ} (f : S n) → Vec (S Term-over X) n → S Term-over X
```

```
{- Example semigroup term -}
```

```
x0Id0y : SemigroupS Term-over (Fin 2)
x0Id0y = _0$ (_0$ (var :: Id $ [] :: []) :: var :: [])
  where  = zero ;  = suc zero
```

```
{- Ever term is a function of its variables -}
```

```
arity : {X : Set} {S : Signature} → S Term-over X → ℕ
arity _ = 0
-- arity (var x) = 1
-- arity (f $ xs) = sum (Vec.map arity xs)
-- Fails termination checking.
```

```
⟦_⟧t : {X : Set} {S : Signature} → (t : S Term-over X) → (A : S Algebra)
```

```

148     → Vec (Carrier  $\mathcal{A}$ ) (arity t) → Carrier  $\mathcal{A}$ 
149    $\llbracket t \rrbracket_t \mathcal{A} = \{!!\}$ 
150
151   data _Equation-over_ (S : Signature) (X : Set) : Set where
152     _≈_ : (lhs rhs : S Term-over X) → S Equation-over X
153
154   lhs rhs : {S : Signature} {X : Set} → S Equation-over X → S Term-over X
155   lhs (l ≈ r) = l
156   rhs (l ≈ r) = r
157
158   {- Example semigroup axiom -}
159   sg-assoc : SemigroupS Equation-over (Fin 3)
160   sg-assoc =   (_≈_ $ ( :: (_≈_ $ ( :: :: [])) :: []))
161               ≈ (_≈_ $ ((_≈_ $ ( :: :: [])) :: :: []))
162   where   = var zero ;   = var (suc zero) ;   = var (suc (suc zero))
163
164   We can now define an equational theory:
165
166   record EquationalSpecfication : Set1 where
167     field
168       -- Interface
169       FuncSyms : Signature
170
171       -- Constraints, with numbers as variables
172       Axioms    : FuncSyms Equation-over  $\mathbb{N}$  → Set
173
174   open EquationalSpecfication
175
176   record _Theory (E : EquationalSpecfication) : Set1 where
177     field
178       Carrier' : Set
179       reify'    :  $\forall \{n : \mathbb{N}\} (f : FuncSyms \mathcal{E} n) \rightarrow \text{Vec Carrier}' n \rightarrow \text{Carrier}'$ 
180
181       algebra : (FuncSyms  $\mathcal{E}$ ) Algebra
182       algebra = record { Carrier = Carrier' ; reify = reify' }
183
184     field
185       satisfy :  $\forall \{e\} \{ _ : \text{Axioms } \mathcal{E} e \} \rightarrow \llbracket \text{lhs } e \rrbracket_t \text{algebra} \equiv \llbracket \text{rhs } e \rrbracket_t \text{algebra}$ 

```

4 WE WANT TO BE SYSTEMATIC ABOUT

Exploring Magma-based theories see [https://en.wikipedia.org/wiki/Magma_\(algebra\)](https://en.wikipedia.org/wiki/Magma_(algebra)) where we want to at least explore all the properties that are affine. These are interesting things said at https://en.wikipedia.org/wiki/Category_of_magmas which should be better understood.

Pointed theories There is not much to be said here. Although I guess 'contractible' can be defined already here.

Pointed Magma theories Interestingly, non-associative pointed Magma theories don't show up in the nice summary above. Of course, this is where Monoid belongs. But it is worth exploring all of the combinations too.

unary theories wikipedia sure doesn't spend much time on these (see https://en.wikipedia.org/wiki/Algebraic_structure) but there are some interesting ones, because if the unary operation is 'f' things like forall x. f (f x) = x is **linear**, because x is used exactly once on each side. The non-linearity of 'f' doesn't count (else associativity wouldn't work either, as `*` is used funnily there too). So "iter 17 f x = x" is a fine axiom here too. [iter is definable in the ground theory]

This is actually where things started, as 'involution' belongs here.

And is the first weird one.

Pointed unary theories E.g., the natural numbers

Pointer binary theories need to figure out which are expressible

more semiring, near-ring, etc. Need a sampling. But quasigroup (with 3 operations!) would be neat to look at.

Also, I think we want to explore

- Free Theories
- Initial Objects
- Cofree Theories (when they exist)

Then the potential 'future work' is huge. But that can be left for later. We want to have all the above rock solid first.

5 RELATIONSHIP WITH 700 MODULES

To make it a POPL paper, as well as related to your module work, it is also going to be worthwhile to notice and abstract the patterns. Such as generating induction principles and recursors.

A slow-paced introduction to reflection in Agda:

<https://github.com/alhassy/gentle-intro-to-reflection>

6 TIMELINE

Regarding POPL:

<https://popl20.sigplan.org/track/POPL-2020-Research-Papers#POPL-2020-Call-for-Papers>

There is no explicit Pearl category, nor any mention of that style. Nevertheless, I think it's worth a shot, as I think by being systematic, we'll "grab" in a lot of things that are not usually considered part of one's basic toolkit.

However, to have a chance, the technical content of the paper should be done by June 17th, and the rest of the time should be spent on the presentation of the material. The bar is very high at POPL.

7 TASK LIST ITEMS BELOW

7.1 DONE JC start learning about org mode

7.2 DONE JC Figure out how to expand collapsed entries

7.3 TODO JC Write introduction/outline

7.4 TODO MA To read:

From monoids to near-semirings: the essence of MonadPlus and Alternative, <https://usuarios.fceia.unr.edu.ar/~mauro/pubs/FromMonoidstoNearsemirings.pdf>.
